**TAMING THE TIDES FOR GREEN-GROWTH ACROSS THE THAMES ESTUARY**

It is widely recognised that, for the economic benefits of the Thames Estuary growth corridor to be realised, the conurbations of North Kent and South Essex need to be connected. At the same time, climate change and rising sea levels are threatening to divide them, with over 110sq.km of the estuary exposed to flood risk. If considered as separate infrastructure projects, improving connectivity and reducing flood risk are very costly. A single system of integrated infrastructure would save substantial costs, reduce the risks and increase the economic benefits.

London is fortunate in that the tidal range at Tower Pier is over 7m. Higher than New York or Shanghai, London is 3.5m above mean sea level and not immediately at risk, if the tides can be tamed. The Thames Estuary acts as a funnel, causing the tides to rise upstream. From Southend Pier to Tower Pier they double in height. A barrier upstream across the tideway would be shorter but the sea walls required along the estuary become higher and longer. Such a barrier at Long Reach, just upstream from the Dartford Crossing, requires a 106km flood defence system, while a barrier between Southend and Allhallows across the Lower Thames Estuary is just 8km long and faces lower tides. Should sea levels rise faster than currently projected the problem would be solved by raising 8km rather than 106km of flood datum, from a lower level.

The Metrotidal Lower Thames Orbital integrates the next generation of London's flood defences with a Crossrail orbital and a floating solar array, to provide substantial green-growth across the Lower Thames Estuary with no increase in carbon audit. The TE2200 flood defences through the 22<sup>nd</sup> century aim to provide a robust system for lower cost and environmental impact and for longer duration than the current TE2100 proposals. The green-growth is achieved through the generation of renewable energy for over 100,000 new homes, along with improved rail connectivity and efficient data storage.

The integrated infrastructure consists of an open-throttle formed by shallow impoundments across Sea Reach that reduce the tidal range upstream in the event of a storm surge, thereby providing London and all areas downstream to the sea with flood defences through the 21st century, while leaving the tideway open for navigation to all existing wharves and docks. The system can then become a full barrier, when required in the 22<sup>nd</sup> century, with the 8km flood datum raised as necessary to meet the rising sea levels.

A rail tunnel formed within the flood barrier impoundments links the eastern limbs of Crossrail to complete a twin-track rail orbital of the Lower Thames Estuary from Central London. The estuary rail orbital with a 4sq.km floating solar array, cycle superhighway and promenade, including wayleaves for data storage, distribution and utilities, provides sustainable connectivity for over a million households, generating green-growth across the Lower Thames Estuary into Essex and Kent. Just 12km of new railway line creates a 132km Crossrail orbital of the Thames Estuary from Central London.

Construction undertaken in the tideway makes use of concrete batching and casting facilities nearby on the Isle of Grain and Hoo Peninsula. Spoil from the tunnel excavations is reused locally for embankments and flood bunds so that the embodied energy of construction and environmental impacts are kept to a minimum. The impoundments protect the estuary from tidal squeeze, thereby saving over 800 hectares of intertidal habitat and avoiding the need for managed retreat on the Isle of Grain.
